Results We collected 364 cases of cervical cancer, account for 58.33% of the cervical samples received in our laboratory. It represents 24.57% of cancers diagnosed in our laboratory during our study and 69% of gynecological cancers. The average age of the patients was 52.45 years with extremes of 26 and 83 years. The peak frequency was in the age group [40 – 49 years]. The presence of cervical mass was the clinical information communicated in n = 194 (53.29%) of the cases. Cancer was diagnosed in n = 326 (89.56%) on biopsy specimens and in n = 38 (10.43%) on surgical specimens. The histological types was squamous cell carcinoma in n = 325 (89.28%), adenocarcinoma in n = 37 (10.16%), and adenosquamous carcinoma in n = 2 (0.54%).

Conclusion Cervical cancer is the most frequently diagnosed gynecological cancer in our laboratory. It mainly concerns the [40 – 49 years old] age group. Squamous cell carcinoma is the predominant histological type.

Abstracts

Objective This study aimed to establish intraoperative diagnostic criteria of sentinel lymph node (SLN) micro-/macrometastasis on the basis of tissue rinse liquid-based cytology (TRLBC) in gynecological cancer.

Methods We enrolled 214 patients with gynecological cancer who underwent rapid diagnosis of SLN metastasis on the basis of TRLBC from a total of 490 SLNs. For slides that were classified as positive for atypical cells on cytological inspection, we counted the number of clusters (an atypical cell mass consisted of three or more cells) and the number of single cells (an atypical cell other than clusters). Receiver operating characteristic (ROC) analysis was applied to determine the efficiency of predicting SLN micro-/macrometastasis.

Results On cytological inspection, 36 slides were classified as positive for atypical cells, while 21 slides (4.3%) were true positive, 15 (3.1%) were false positive, and 454 (92.6%) were true negative. There were no false negative results in this study. The area under the ROC curve for the number of cluster was superior to that for the number of single cells for distinguishing micro-/macrometastasis from negative/isolated tumor cells (0.86 vs. 0.67, P = 0.032). The optimum cut-off value of the number of clusters was 5 for distinguishing these two categories.

Conclusions TRLBC is a highly sensitive alternative for detecting SLN metastasis as a rapid intraoperative diagnosis. Counting the number of atypical cell clusters might be useful for distinguishing micro-/macrometastasis from isolated tumor cells.

IMPACT OF THE SARS-COVID PANDEMIC ON THE CLINICAL AND RESEARCH MANAGEMENT OF PATIENTS WITH GYNECOLOGICAL MALIGNANCIES: AN ONGOING SURVEY IN THE PAN-ARABIAN REGION

1S Nasser, 2A Awad, 1J Sehouli*. 1Charite Comprehensive Cancer Center, Germany; 2Mansoura University Hospitals, Egypt

The novel coronavirus disease (COVID-19) is a global public health emergency that has impacted medical professionals, infrastructures and the care of patients with gynecological malignancies.

The pandemic has also caused disruption to research and clinical trials worldwide. We conducted a Survey within the Pan-arabian Region to evaluate the impact of the COVID-19 Pandemic on the management of patients with gynecological malignancies from the multidisciplinary physicians’ perspective, with particular focus on clinical infrastructures, trial participation and maintenance therapy. The survey is designed to capture the dynamic changes observed with the development of the pandemic in order to build robust emergency algorithms tailored to gynecological oncology patients globally in the future.

HIGH TUMOR-STROMA RATIO IN ESTROGEN RECEPTOR-POSITIVE BREAST CANCER IS CORRELATED TO POOR HISTOPATHOLOGICAL PARAMETERS

1D Bacha, 2A Ben Amor*, 3A Halousani, 1A Lahmar, 1S Ben Slama, 1Mongi Slim Hospital, Pathology Department, University Tunis El Manar, Tunisia; 2Mongi Slim Hospital, Obstetrics and Gynecology Department, University Tunis El Manar, Tunisia

Introduction In breast cancer, attention has focused on the prognostic value of tumor-stroma ratio (TSR), mainly in the triple-negative subtype, which generally has a poor prognosis.

Little prognostic data are available for other carcinoma types.

Objective To determine the prognostic value of TSR in estrogen receptor (ER) positive invasive breast carcinomas.

Methods TSR was measured in hematoxylin and eosin-stained surgical specimens of 70 consecutive EP positive breast carcinomas. Tissue from the most invasive part of the tumor was used. A part of the sample was selected where both tumor and stromal tissue were available. Scoring percentages were given per 10-fold per image field.

Tumors with a low ratio had ≥50% of stroma and a high ratio had <50% of stroma.

The relationship of TSR with routinely used prognostic histopathological parameters (tumor size, grade, mitotic activity index, lymph-node status, vascular invasion, and HER2 status) was analyzed.

Results All tumors were of no special type. The mean age of patients was 65 years. There was no multifocality. Sixty percent of tumors had a high ratio and 40% a low ratio.

High ratio tumors were significantly correlated with large size (p=0.02), grade 3 (p=0.045), presence of vascular invasion (p=0.0034) and lymph node metastasis (p=0.0012). No significant association was found with the mitotic activity index and HER2 status.

Conclusion High TSR was related to poor histopathological parameters in EP positive carcinomas, contrasting data in triple-negative breast cancer, and highlighting the importance of considering ER status when interpreting the prognostic value of TSR.
