Indocyanine green (ICG) is a promising tracer in sentinel lymph node (SLN) procedure in patients with early stage cervical cancer. Our objective was to assess the differences in overall and bilateral detection rates of ICG versus technetium-99m (99mTc) with or without blue dye.

Methods We searched Medline, Embase and the Cochrane Library from inception to April 1st, 2020. Studies reporting on a direct comparison of SLN detection with ICG versus 99mTc ± blue dye in early stage cervical cancer were included. Two reviewers independently selected eligible articles and assessed study quality using the ROBINS-I tool. The overall and bilateral detection rates were pooled with random-effects meta-analyses.

Results From 112 studies retrieved, nine met selection criteria. One study was excluded due to a critical risk of bias. The remaining eight cohort studies of limited quality (two prospective; six retrospective) included 654 patients. No significant differences were found in the pooled overall detection rate of ICG versus 99mTc ± blue dye (98.7% (95%CI, 96.5–100.0%) versus 95.6% (95%CI, 92.1–99.2%), respectively). Use of ICG significantly increased bilateral detection rates compared with 99mTc ± blue dye; 91.5% (95%CI, 82.3–100%) versus 71.7% (95%CI, 64.7–78.7%), respectively, with an OR of 5.17 (95% CI, 1.88–14.21, P 0.01). Five studies reported on patients in partial overlap of each other. No adverse events related to ICG were described.

Conclusion/Implications In early stage cervical cancer, ICG appears to be superior to the 99mTc with or without blue dye in terms of bilateral SLN detection. Additional prospective studies are needed.
implemented a multi-disciplinary surgical team including gynaecological oncologists, colorectal, hepatobiliary and upper GI surgeons to increase gross macroscopic resection rates.

**Methods** Two cohorts were used. Cohort A was a retrospectively collated cohort from 2006–2015. Cohort B was a prospectively collated cohort of patients initiated in 2017. A multidisciplinary approach to preoperative medical optimisation, intra operative management and postoperative care was implemented in 2017. Patients in cohort B with upper abdominal disease were offered primary cytoreduction ± HIPEC. Prior to 2017 patients with upper abdominal disease received neoadjuvant chemotherapy.

**Results** This study include 146 patients in cohort A (2006–2015) and 93 patients in cohort B (2017–2019) with stage III/IV ovarian cancer. The overall complete macroscopic resection rate (CC-0) increased from 58.9% in cohort A to 67.7% in cohort B. The rate of primary CRS increased from 38% (55/146) in cohort A to 42% (39/93) in cohort B. The CC-0 rate in those who had primary CRS increased from 49% in Cohort A to 77% in Cohort B. Major morbidity remained stable throughout both study periods.

**Conclusions** Our data demonstrates that the implementation of multidisciplinary team intraoperative approach and a meticulous approach to preoperative optimisation has resulted in a significant improvement in complete resection rates particularly in women offered primary CRS.

RACIAL DISPARITIES ASSOCIATED WITH INCREASING INCIDENCE OF EPITHELIAL OVARIAN CANCER IN THE UNITED STATES

R Ratnaparkh*, C Liao, A Chan, C Tian, KM Darcy, L Maxwell, DS Knapp, JK Chan. 1Department of Obstetrics and Gynecology, Stanford University, USA; 2Kaohsiung Veterans General Hospital, Taiwan; 3Division of Gynecologic Oncology, Palo Alto Medical Foundation, California Pacific Medical Center, Sutter Health, USA; 4Walter Reed National Military Medical Center, USA

Introduction The incidence of ovarian cancer has decreased in the United States since the 1980s, predominantly driven by decreasing incidence in Non-Hispanic Whites. The purpose of this study was to identify racial disparities in histologic subtypes of epithelial ovarian cancer.

**Methods** Data were obtained from the United States Cancer Statistics (USCS) database from 2001 to 2016. Age-adjusted incidence per 100,000 women and annual percent change (APC) in incidence were calculated using SEER*Stat and Joinpoint Software.

**Results** Of 319,257 women diagnosed with epithelial ovarian cancer, 79.9% were Non-Hispanic White, 7.8% were Non-Hispanic Black, 7.9% were Hispanic, 3.5% were Asian/Pacific Islanders, and 0.9% were Other/Unknown. Over a sixteen-year period, the overall incidence of epithelial ovarian cancer decreased 1.96% per year (95% CI -2.13, -1.78, p < 0.001). However, in Non-Hispanic Blacks (APC 0.84%, 2.72%) and Asian/Pacific Islanders (APC 0.94%, 2.09%), the incidence of serous and clear cell carcinoma respectively have both increased significantly in the same period. Hispanics had a significant decrease only in incidence of endometrioid (-2.1%) and mucinous (-4.23%) histologies (figure 1). This contrasts the decrease in incidence for Non-Hispanic Whites seen across all histologic subtypes.

**Conclusions** Persistent racial disparities are unmasked when analyzing trends in ovarian cancer incidence by histologic subtype. Non-Hispanic Blacks and Asian/Pacific Islanders continue to have an increasing incidence of serous and clear cell ovarian carcinomas.
