terms of specificity and sensibility (Sp 100%, Sn 77.6%) to identify frail group. 36% of patients resulted frail. Frailty was associated with longer hospitalization after surgery (11.5 days vs 8.3 days, \( p = 0.01 \)). No differences occurred in the incidence of post-operative adverse events, but grade III and IV complications were observed exclusively in 2 frail women. Only 38.5% of frail patients completed chemotherapy treatment; delay in chemotherapy administration has been reported in 77% of frail patients (vs 17.6% in ‘fit group’, \( p = 0.008 \)) and dose reduction in 70.6%. Thrombocytopenia (69.3% vs 0%, \( p = 0.002 \)) and anemia (77% vs 29.4%, \( p = 0.002 \)) were more prevalent in the frail group, as well as non-hematological adverse events.

Conclusions Our tool seems to effectively stratify elderly patients with gynecological cancers according to frailty, in order to choose the best treatment for frail women and avoid undertreatment in fit ones.

144 OVARIAN CARCINOMA LONG-TERM SURVIVORS: A LARGE SINGLE CENTER STUDY AT THE TÜBINGEN UNIVERSITY WOMEN’S HOSPITAL

1S Mittelstadt*, 1M Grube, 1T Engler, 1CB Walter, 1E Oberlechner, 1J Pasternak, 1U Hürst, 1B Krämer, 1E Grischke, 1SY Brucker, 1AK Fischer, 1A Staebler, 1A Hartkopf, 1S Kimmoss. 1Department of Women’s Health, Tübingen University Hospital, Germany; 2Department of Pathology and Neuropathology, Tübingen University Hospital, Germany

Introduction/Objectives Most ovarian carcinoma patients present with advanced-stage disease and outcome is fatal in many cases. However, the biological behavior of ovarian carcinoma can be quite variable and long-term survival is reported in up to 30% of patients. It is the aim of this project to identify characteristics associated with long-term survival.

Methods Patients diagnosed with ovarian carcinoma between 2000 and 2012 were identified and follow-up data was collected. In patients who survived for at least 8 years a detailed chart review was performed.

Results A total of n=749 patients with adequate follow-up was identified, of which n=225 (29%) were alive for at least 8 years after diagnosis. Median follow-up was 11.7 years. Median age at diagnosis was 53.5 years. 57% were diagnosed in advanced stage (≥FIGO IIIB). Histotype was found to be high-grade serous in 53%, low-grade serous in 7.9%, mucinous in 7.4%, clear cell in 3.7% and endometrioid in 20% of patients. Median progression free survival was 5.0 years in early, and 2.8 years in advanced-stage patients.

Conclusion Despite ovarian carcinoma being perceived as a highly fatal disease, long-term survival is observed in a substantial number of patients and is not limited to early-stage or low-risk disease. Although prognostic factors are well established, further research of patient characteristics, genetic features and treatment modalities will help to better understand factors contributing to long-term survival. We encourage the scientific community to be aware of this special patient group, which may be key to improving our daily approach to ovarian carcinoma patients.
