rearranging the position of the ports and bringing them closer to the tip of the femoral triangle. A 30 degree telescope helped in visualising the tip of the triangle better to remove the nodal tissue enbloc at completion of surgery.

**Results** Improved techniques led to easy identification of sattorus and standardization of the procedure.

**Conclusion** Issues and tips for improvement in surgical techniques especially in novel areas like robotic Inguino-femoral node dissection surgery are addressed.

**Introduction/Background** ECT utilises pulsed electrical current to transiently increase cell membrane permeability to the cytotoxic agent, bleomycin. We present the use of ECT in patients with recurrent gynaecological malignancy previously treated with a combination of surgery or radiotherapy, experiencing symptoms from cutaneous lesions. This report presents evidence of the role for ECT in second and third line treatment.

**Methodology** Between July 2017 and August 2019, 6 patients with cutaneous recurrence of gynaecological malignancy (5 vulvar SCC and 1 high grade serous ovarian cancer) were treated with intra-tumoural bleomycin (9000 iu or 15000 iu, dependent on tumour volume) and pulsed-probe electroporation. Response was assessed clinically in routine follow up or procedure pain scores were collated as part the quality of life evaluation.

**Results** Median treated tumour diameter was 6 cm (range 2 – 12 cm). Pain scores peaked between day 2 and day 7 post-procedure. The median progression free interval was 3.6 months (range 0.8 – 6.7 months).

Following ECT treatment 2 patients continued to receive supportive care. Two patients underwent repeat treatment with ECT and reported symptom improvement with each treatment. Due to further progression two patients underwent radical surgery and one patient received palliative chemotherapy.

**Conclusion** ECT should be considered for patients with symptomatic cutaneous recurrence of gynaecological malignancy who have previously had multi-modal treatment. It can achieve symptom control and reduce the need for radical surgery in this palliative setting.

**Introduction/Background** Surgical treatment of advanced vulvar malignant tumors usually requires immediate reconstruction. Large defects after pelvis, vagina, vulva, groin and perineum wide excision require closure with the usage of difficult reconstructive techniques. In this case the most suitable myocutaneous flap for reconstruction is rectus abdominis muscle flap, which provides the biggest volume of tissues to cover those large defects.

**Methodology** Woman 67 y.o. initially presented with the combined treatment of cervical cancer stage IIIb. Within 5 month was diagnosed the lymphedema in the left lower extremity. Approximately 2 years she presented the vulvar tumor measured 15 × 10 cm. A biopsy was performed the lymphangiosarcoma.

**Results** In the National Cancer Institute of Ukraine we investigated a new variation of large defects reconstruction using rectus abdominis muscle flap. To collect a donor flap, we perform 3 arcuate incisions: one vertical by the medial line around the umbilicus, and two oblique incisions towards upper anterior iliac spine of one of the sides. In this way we use only one half of the abdomen, and in case of any complications with the flap or relapse of the disease we will have the second donor site for possible future re-operation. There is a narrow ‘bridge’ of tissues we leave between the excised donor and recipient sites. It is extremely important to preserve blood supply not only to the flap, but also to the ‘bridge’ to avoid complications. We perform a tunnel under the ‘bridge’ as small as possible to preserve all inferior epigastric vessels, but enough to transfer the flap and not to squeeze the pedicle. After the surgery we have a half-inverted Y-shaped scar on the sides of the abdomen, an inverted triangular scar at the pelvis area, circumumbilical scar and a short vertical scar on the flap to imitate pudendal cleft with central structures of vulva (urethra and vaginal tube).

**Conclusion** We consider our variation of this type of surgery the most safe and efficient, with the opportunity of re-operation if needed. Advanced vulvar malignancies are quite rare, so we will keep working on development and enhancement of the technique to help these patients.
