was used as newly diagnosed maintenance treatment in 25 (58.1%) patients, as treatment for ≥1 line recurrence treatment in 14 (32.6%) patients, and as platinum-sensitive recurrent maintenance treatment in 4 (9.3%) patients. Overall, 28 (65.1%) patients experienced ≥1 grade hematologic AEs, which included leukopenia (37.2%), anemia (34.9%) and thrombocytopenia (39.5%). Only 10 (23.3%) patients had grade 3/4 AEs including leukopenia (9.3%), anemia (7.0%) and thrombocytopenia (11.6%). Until last follow up, the median time for the occurrence of leukopenia, anemia and thrombocytopenia were 30 (range: 7, 162), 34 (range: 7, 108) and 20 (range: 13, 180) days, respectively. No deaths were reported. Of those patients who experienced AEs during treatment, the dose was reduced in 4 (14.3%) patients, and treatment was interrupted in 9 (32.1%) patients. Additional recombinant human granulocyte colony stimulating factor (n=5, 17.9%), erythrocyte (n=2, 7.1%) and recombinant human thrombopoietin (n=5, 17.9%) were provided for treating the AEs. After intervention, 8 (18.6%) patients restart the treatment and only 1 (2.3%) patient discontinued the treatment.

Conclusion The incidence of hematologic AEs in real-world experience was lower than reported by niraparib 300 mg/day in ENGOT-OV16/NOVA trial. In addition to maintenance treatment in the first line, the patients in platinum-sensitive recurrence treatment and later line treatment might benefit from ISD niraparib.

Introduction/Background Integrin beta-like 1 (ITGBL1) is a poorly characterized protein comprised of ten EGF-like repeats. Our previous studies suggested that higher ITGBL1 mRNA expression level in the tumor is related with shorter survival of ovarian cancer patients. 1, 2 Subsequent functional in vitro studies revealed that ITGBL1 overexpression in ovarian cancer cells resulted in the altered adhesion, migration and invasiveness, while it had no effect on proliferation rate and the cell cycle. ITGBL1-overexpressing cells were significantly more resistant to cisplatin and paclitaxel, 3 major drugs used in OC treatment. 4 In the current study we analyzed gene expression profiles of ITGBL1-overexpressing and control ovarian cancer cells and investigated ITGBL1 influence on ovarian cancer cell signaling pathways.
Methodology ITGBL1 coding sequence was PCR-amplified from cDNA and cloned into pLNCX2 vector. Retroviral system was used to obtain two ovarian cancer cell lines: OAW42/ITGBL1(+) and SKOV3/ITGBL1(+) with overexpression of ITGBL1. Control cell lines were obtained by transduction with an empty vector. RNA was isolated from wild type, ITGBL1-overexpressing and control cells. DNA microarray experiment was performed using GeneChip™ Human Transcriptome Array 2.0 (Affymetrix, Santa Clara, CA, USA) according to the manufacturer’s instructions. Bioinformatical analysis was carried out in R environment (version 3.5.3) with Bioconductor packages.
Results Using Principal Component Analysis, an unsupervised method of data analysis, we selected gene sets related to major sources of variability in our dataset. Then, by performing Gene Set Enrichment Analysis we found 76 and 146 significantly affected cellular signaling pathways (in OAW42 and SKOV3 cell line, respectively). Majority of them (22 and 44, respectively) were related to extracellular matrix structure and function, integrin signaling, focal adhesion, cell junction, cellular motility, ERBB2 and ERBB4 signaling, etc.
Conclusion Global gene expression analysis revealed that signaling pathways affected by ITGBL1 overexpression were mostly those related to extracellular matrix organization and function, integrin signaling, focal adhesion, cellular communication and motility. These results are concordant with functional changes observed in ITGBL1-overexpressing cells, like altered adhesiveness, enhanced motility and invasiveness. Overall, our results indicate that higher expression of ITGBL1 in ovarian cancer cells is associated with features that may worsen clinical course of the disease.

423 FIBRONECTIN AND PERIOSTIN AS PROGNOSTIC MARKERS IN OVARIAN CANCER
1Katarzyna A Kujawa, 2Ewa Zembala-Nożyńska, 3Alexander J Cortez, 4Jolanta Kupniarczyk, 1Katarzyna M Lisowska, 1Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch; Center for Translational Research and Molecular Biology of Cancer; 2Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch; Center for Translational Research and Molecular Biology of Cancer; 3Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch; Tumor Pathology Department; 4Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch; Department of Biostatistics and Bioinformatics, Center for Translational Research and Molecular Biology of Cancer

Introduction/Background In our previous microarray study we identified a 96-gene prognostic signature associated with the shorter overall survival (OS) of ovarian cancer patients. 1 Two genes from this signature, both coding for extracellular matrix proteins, were objects of the present study: FN1 and POSTN. We analyzed, by immunostaining, expression of encoded proteins in the independent set of ovarian cancer samples and evaluated its correlation with clinical, pathological, and molecular features.
Methodology Ovarian cancer samples from 108 patients were analyzed by immunohistochemistry using rabbit anti-human fibronectin polyclonal antibody (1:3000 dilution, A0245, Dako, Glostrup, USA) and rabbit anti-human peristin...
polyclonal antibody (1:200 dilution, ab14041, Abcam, Cambridge, UK). Correlation with survival was evaluated with Cox proportional-hazards model and Kaplan–Meier estimator with log-rank test. Two-sided p-values <0.05 were considered statistically significant. Analyses were carried out using Statistica 13.1 (TIBCO Software Inc., Palo Alto, CA, USA).

**Results** We observed that the higher expression of FN1 and POSTN was associated with shorter OS (log-rank: p-value 0.003 and 0.04 respectively). Next, we analyzed performance of the combined FN1&POSTN score calculated as a sum of individual FN1 and POSTN scores. We hypothesized that two-protein score would be more robust than evaluation of single proteins. Indeed, Cox regression demonstrated that FN1&POSTN score was an independent prognostic factor for OS (HR = 2.16; 95% CI: 1.02–4.60; p-value 0.044). However, we observed two outliers: out of the entire cohort one patient with a score 2 (indicating favorable prognosis) had the shortest OS and one patient with score 6 (indicating worst prognosis) had the second longest OS (131.17 month). These observations indicate that the FN1&POSTN score behaves similarly to classical prognostic factors: some patients having good prognosis, progress quickly and die early, while some patients with bad prognosis live unexpectedly long. In addition, our study showed that expression of fibronectin and periostin was associated with the source of OC sample: metastases showed higher expression of these proteins than primary tumors (chi2 test, p-value 0.024 and p-value 0.032). Elevated expression of fibronectin and periostin was also more common in fallopian cancers than in ovarian cancers.

**Conclusion** In summary, we found that the joint FN1&POSTN score is an independent prognostic factor for OS in ovarian cancer patients. Moreover, our results support the role of the cancer microenvironment in tumor progression and prognosis and add to the concept that some ovarian cancers originate from fallopian tube epithelium.

**425 HIPEC IN OVARIAN CANCER: THE FIRST CASE-CONTROL STUDY IN MEXICAN PATIENTS**

1Juan Manuel Medina-Castro, 2Aely Gonzalez, 3Flavia Morales, 4Maria Antonia Morales. 1Grupo Oncológico de Toluca; Martin Alonso Pinzón 135; 2Instituto Nacional de Cancerología; National Cancer Institute Mexico; Gynecology Oncology, 3National Cancer Institute Mexico; Medical Oncology; 4State National Cancer Center; Radiology

**Introduction/Background** Describe the global survival of ovarian cancer patients treated with HIPEC procedure. Compare overall survival (OS) and progression-free survival (PFS) among ovarian cancer patients who underwent cytoreduction and HIPEC procedure vs patients treated with systemic chemotherapy.

**Methodology** Cases: patients treated with cytoreduction and HIPEC (N=46)

- Controls: patients treated with systemic chemotherapy (N=92)
  - Follow-up: 2007–2017
  - PFS was calculated from the beginning of the treatment to the date when progression, death or the last visit was documented. OS was calculated from the beginning of the treatment to the death or to the last known follow-up.

**Results** The estimated median OS in the HIPEC group was 99.1 months vs 38.9 months in the control group (p=0.0002). PFS was 32.8 months in the HIPEC group and 17.8 months in the control group (p=0.05).

**Conclusion** Platinum resistance plays an important role in patient survival, with a difference of 40 months between those who are resistant and those who are not at the moment of HIPEC. This study suggests that CRS and HIPEC in patients with recurrent complete cytoreduction (CCR0) was performed in 33 patients (71.7%) and optimal (with residual of less than 0.5 cm) in 13 patients (28.3%). Severe complications occurred in 11 patients (37.93%). Ovarian cancer may be beneficial compared to conventional secondary debulking or systemic therapy as treatment alone. The measurement of OS from initial diagnosis is substantially modified to more than 104 months, a figure not seen before in advanced or recurrent disease of this neoplasm.

**Disclosures** The effort of the surgical oncology community to find the ideal patient and the ideal moment for this procedure should be directed not only to treatment, but to a sequence that offers patients a possibility of cure.
