patients with breast cancer (n=65), cervical cancer (n=32), haematological malignancies (n=30) and melanoma (n=21). Questions were asked regarding possibilities of ionized imaging, chemotherapy, hormonal therapy or immunotherapy during pregnancy and possible effects on the child, the sequence of the different treatment components and questions on fertility. Response rate of the questionnaire was 54%. Overall satisfaction with the recommendations of the MDT was high, and 94% of the respondents informed their patients about consulting the MDT and felt supported by the received recommendations.

**Conclusion** A national MDT for cancer and pregnancy is frequently consulted and highly appreciated by physicians. Next to that, it increases expertise of its members about this rare coincidence of cancer and pregnancy. We highly recommend to establish an (inter)national MDT in each country. Figure 1 shows the important steps necessary to establish an MDT for cancer in pregnancy based on our experience.

10.1136/ijgc-2021-ESGO.239

**Introduction/Background** This study was undertaken to evaluate and compare CA125 and HE4 serum concentrations in the early postpartum period.

**Methodology** In a prospective designed, monocentric study (Department of Gynecology & Obstetrics, General and Teaching Hospital, Celje, Slovenia, EU), 68 women who were in the 1-3rd day of postpartum period were included in the study.

HE4 and CA125 levels were obtained and analysed with regard to each day of postpartum period (1st, 2nd and 3rd day after delivery) as well as regarding the method of delivery (vaginal delivery; n=46, elective (ElCS); n=15 and emergency caesarean section (EmCS); n=8).

CA125 and HE4 levels were measured in consideration of their reference intervals less than 35 IU/ml and less than 140 pmol/l, respectively (Elecsys CA 125 II® assay and Elecsys HE4® assay, Roche Diagnostics Ltd., Rotkreuz, Switzerland).

Data were analysed by ANOVA (MedCalc Software, Mariakerke, Belgium).

**Result(s)** The CA-125 levels were frequently above the conventional cut-off limit of 35 IU/ml and less than 140 pmol/l, respectively (Elecsys CA 125 II® assay and Elecsys HE4® assay, Roche Diagnostics Ltd., Rotkreuz, Switzerland).

Regarding the method of delivery, women in the vaginal delivery group had seemingly higher levels of CA125 than the women in both caesarean section groups (44,0 IU/ml vs 29,7 IU/ml (ElCS) and 21,5 IU/ml (EmCS), respectively; p=0,015).

**Conclusion** According to our preliminary results, HE4 is more reliable marker of malignancy during the early postpartum period than CA125.

**Abstract 324 Figure 1**

**Abstract 324 Figure 2**

= 54,3 pmol/l; Group III, n =5, 3rd day after delivery, mean = 49,2 pmol/l, p= 0,096).

Regarding the method of delivery, women in the vaginal delivery group had significantly lower levels of HE4 than the women in both caesarean section groups (54,5 pmol/l vs 65,7 pmol/l (ElCS) and 61,1 pmol/l (EmCS), respectively; p=0,015.

**Conclusion** According to our preliminary results, HE4 is more reliable marker of malignancy during the early postpartum period than CA125.

**CONSERVATIVE SURGERY AND OVERALL SURVIVAL IN YOUNG WOMEN WITH A DIAGNOSIS OF BORDERLINE OVARIAN TUMOR**

M Laseca Modrego*, O Arembíia Sanchez, D González García-Caro, AF Rave Ramirez, A Martín Martinez. Maternal Child Hospital of the Canary Islands, Oncology Gynecology Department, Las Palmas de Gran Canaria, Spain

10.1136/ijgc-2021-ESGO.240

**Introduction/Background** Radical surgery is the main treatment for Borderline Ovarian Tumors. Surgery includes hysterectomy, double adnexectomy, omentectomy and appendectomy if the histological line is mucinous.
Due to the excellent prognosis, some authors affirm that it is possible to perform a conservative surgery in young women who have not fulfilled their reproductive desire, without having repercussions in terms of overall survival.

The objective of the study was to know the treatment and the overall survival of the Borderline Ovarian Tumors in young women.

Methodology A retrospective cohort study was conducted. The study period was from January 2012 to January 2020. A total of 131 women with Borderline Ovarian Tumors were included in the study. Information was collected about: demographic data, diagnosis, type of surgery performed, disease-free survival, and overall survival. Two cohorts were established: conservative treatment (n = 37) vs radical treatment (n = 94).

Result(s)* 131 women with a diagnosis of Borderline Ovarian Tumors were diagnosed, representing 16.7% of all the malignant ovarian tumors within this period (n = 784). 91.5% were diagnosed in Stage I according to the FIGO classification and the most histological line frequent was the mucinous (49.2%). The risk of global relapse was 6.2% and overall survival was 95.4%.

Regarding the group of patients who underwent conservative surgery, the risk of relapse was 13.5% (n = 5) compared to 3.2% (n = 3) in the group radical treatment, (p = 0.042).

The Overall survival was 100% in women with conservative surgery compared to radical surgery, 94.6% (p = 0.130).

Conclusion* Borderline Ovarian Tumors present excellent prognosis, obtaining great positive results in overall survival regarding the performance of conservative surgery in young women with unfulfilled reproductive desire.

SUCCESSFUL LIVE BIRTH TWINS AFTER CHEMOTHERAPY DUE CARCINOMA OF COLON DURING PREGNANCY’S: A CASE REPORT

Due to the fact that the patient has a history of colon cancer, we performed a conservative surgery during pregnancy, and the patient was able to deliver twin babies.

537 FERTILITY SPARING TREATMENT IN PATIENTS WITH ENDOMETRIAL CANCER (FERT-ENC) FROM THE SPANISH INVESTIGATIONAL NETWORK GYNECOLOGIC ONCOLOGY GROUP

Introduction/Background* The primary objective was to evaluate the response rate of conservative treatment in endometrial cancer and the secondary objective was to assess oncological, fertility and obstetric outcomes in fertility preservation patients.

Methodology This was a multi-centre, observational, retrospective study of endometrial cancer patients who underwent fertility-sparing treatment in Spanish centres (January 2010–2020). Seventy-three patients with stage IA, endometrioid adenocarcinoma of the uterus were included in the study.

Result(s)* The levonorgestrel intrauterine device (LNG-IUD) was the most used method (53.4%), followed by megestrol acetate (20.5%) and medroxyprogesterone acetate (16.4%).

Complete response rate (LNG-IUD 87.2% vs. others 58.8%; p = 0.01). Surgical treatment (at least hysterectomy) was completed in 44 (60.3%) patients. Four (5.3%) patients presented with relapse after surgery being associated with it the final stage FIGO III (p = 0.036), myometrial invasion >
