SExuality After Breast Cancer Surgery in Postmenopausal Women

Objectives The main objective of this study was to evaluate the sexual function in married menopausal women after surgery for non metastastic breast cancer.

Methods This is a prospective cohort-type study of 200 menopausal women diagnosed then operated on for breast carcinoma between January 2018 and March 2020. Patients were randomized after a multidisciplinary consultation in 2 groups: G1 with patients who had conservative breast surgery and G2 with those who had a mastectomy. Patients with immediate or delayed postoperative breast reconstruction were excluded. The data collection was done in an individual interview, in which 4 validated standardized psychometric assessment scales were used: The Arab Female Sexual Function Index (ArFSFI) for evaluation of sexual function, The Locke and Wallace Marital Adjustment Test (MAT) for Assessment of Spousal Agreement, The Hospital Anxiety and Depression Scale (HAD-S) for Assessment of Anxiety & Depression, The Body-Esteem Scale for Adolescents and Adults (BESAA) for the evaluation of the body image.

Results The two groups were comparable in terms of age and socio-economic characteristics of the patients and their spouses. The mean total FSFI scores were comparable (22 in G1 vs 24.5 in G2, p = 0.084). There was a positive correlation between the husbands’ education level and the feminine sexual function (p = 0.042) and between marital agreement and sexual function (p = 0.004).

Conclusions The technique of breast surgery for breast cancer does not influence the sexual function in menopausal women.

Concordance in Molecular Profiles of Invasive Breast Cancer Between Core Needle Biopsy and Definitive Operative Specimen Analysis

Objectives The core needle biopsy (CNB) is an attractive alternative to surgical biopsy for the purpose of characterizing completely a malignant breast lesion for a tailored management. The purpose of this work is to study the concordance of the molecular profile of invasive breast cancer between the CNB and definitive pathology examination.

Methods We conducted a case-control study where each subject was her own control, including all patients with primary malignant tumors of the breast, collected prospectively, in our Department of Pathology and Cytology and treated at the Department of Gynecology and Obstetrics of the same hospital from January 1, 2015, to July 31, 2017. The studied molecular profile parameters were estrogen receptors (ER), progesterone receptors (PR), HER2 receptors (HER2), and Ki67.

Results We included 521 patients. The concordance between CNB and definitive postoperative specimen analysis with regard to the molecular profile parameters in invasive breast cancer was respectively of 100% and 96.3% for ER and PR, with an excellent agreement (respectively, k=1 and k=0.905). The agreement in the diagnosis of tumors HER 2 overexpression was strong (k=0.679). There was a difference between Ki 67 tumoral status (cut off at 20%) in CNB versus definitive postoperative specimen analysis in 53.1% of the cases with a weak agreement (k=0.193). Consistency between CNB and postoperative specimen analysis in the distinction of luminal A tumors was 72.8%, 66.7% for luminal B, 90.1% for Her2 type and 86.4% for the basal type.

Conclusions CNB was reliable in determining the hormonal receptors’ status and the HER2 negative invasive breast cancer.

Evaluation of the Extemporaneous Pathological Examination of Axillary Sentinel Lymph Node Detected with Blue Dye

Objectives The evolution of the practice and recommendations regarding the axillary lymph node exploration in breast cancer patients tends toward promoting the sentinel lymph node as a gold standard in clinically N0 patients. This study aims to evaluate the accuracy and conformity of the extemporaneous pathological examination (EPE) with the definitive pathology examination (DPE) of the sentinel lymph node biopsy (SLNB) detected only with blue dye.

Methods We did a retrospective study including all the early-stage breast cancer patients (cT1/2N0) who underwent an axillary SLNB procedure with blue dye in our department of gynecology and obstetrics from 2008 to 2017. We did evaluate the performances of the EPE of the axillary sentinel lymph node by calculating the sensitivity, specificity, false positive, false negative, positive predictive value, negative predictive value, diagnostic efficacy, and the Youden index.

Results We have registered 441 procedures of EPE of axillary SLNB. When confronting the EPE response to the final response, we found that the sensitivity was 90.72%, the specificity 100%. There were no false-positive and 3.30% of false negatives. The positive predictive value was 100% and the negative predictive value 95.10%. The diagnostic efficacy of the EPE was 96.46% and the Youden index 0.91.

Conclusions The EPE is a good tool to evaluate blue dye-detected axillary sentinel lymph nodes during the surgery for early breast cancer.

Predictive Factors of Total Response to Neoadjuvant Chemotherapy (NAT) in Breast Cancer Patients: A Retrospective Observational Study

Objectives The main objective of this study was to evaluate the total response to neoadjuvant chemotherapy for breast cancer patients.

Methods We included 102 patients with breast cancer treated with neoadjuvant chemotherapy between January 2018 and March 2020. The concordance between the extemporaneous pathological examination and the definitive pathological examination was evaluated.

Results The concordance between the extemporaneous pathological examination and the definitive pathological examination was 96.3% for ER and PR, 95.1% for HER2, and 90.1% for Ki67.

Conclusions The extemporaneous pathological examination is a reliable tool for evaluating the total response to neoadjuvant chemotherapy in breast cancer patients.
**Objectives**
This is an observational study with the aim to evaluate predictive factors of response to NAT in patients with breast cancer.

**Methods**
It is a retrospective study included 21 patients who received neoadjuvant chemotherapy between 2015 and 2019 at Salah Azaiez Institute Tunisia. We collected, socioodemographics (age, gender, and marital status); tumor: localization, staging.

**Results**
Our study included 21 patients who achieved breast pCR, between 2015 and 2019, 21 patients were included. The median age was 48 years (range 30–68). All patients had breast cancer and received neoadjuvant chemotherapy. Two patients were diabetic, 3 patients had high blood pressure and 2 had dyslipidemia. The majority of the tumor had a high grade nuclear (14). The majority of molecular profile was tripe negative (6 cases). The evaluation of the response based on imaging firstly and histological examination. Clinically all patient had a complete response. 17 patients underwent radical surgery and 4 conservative surgery. The evaluation of these patients showed that 16 of theme developed recurrence. We concluded that age, nuclear grade, histological type did not effect the response of chemotherapy but this results is insufficient because of the shortage of the serie.

**Conclusions**
To date, no tumour biological factor is available for clinical use in the prediction of chemotherapy response in advanced breast cancer other than oestrogen receptor status, which predicts response to hormonal therapy.

**NUTRITIONAL STATUS AND QUALITY OF LIFE OF BREAST CANCER PATIENTS NEEDING FOR RESPONSE TO NEOADJUVANT CHEMOTHERAPY: ABOUT 19 PATIENTS**

M. Bouhani*, S. Kammoun, S. Sakhri, H. Bouaziz, A. Goucha, R. Chargui, M. Driss. Salah Azaiez Institute of Oncology, Surgical Oncology, Tunis, Tunisia

10.1136/ijgc-2021-IGCS.97

**Objectives**
The aims of this study were to report nutritional status in 19 patients with cancer requiring neoadjuvant chemotherapy and to study the influence of nutritional status on their quality of life.

**Methods**
It is a retrospective study included 19 patients who received neoadjuvant chemotherapy between 2015 and 2019 at Salah Azaiez Institute Tunisia. We collected, socio-demographics (age, gender, and marital status); tumor: localization, staging, health status (performance status according to WHO classification, usual weight and body mass index (BMI)).

**Results**
Between 2015 and 2019, 19 patients were included. The median age was 52 years (range 30–72). All patients had breast cancer and received neoadjuvant chemotherapy. 13 patients were menopaused, two patients were diabetic, 14 patients had high blood pressure and 4 had dyslipidemia. BMI was normal in 6 cases, overweight in 4 cases and obesity in 9 cases. The majority of the tumor were classified T4B. 17 patients had invasive ductal carcinoma. During chemotherapy, 3 patients follow vegetables and fruit diets, 7 follow mixed diets and 9 follow western diet. Three patient had a sport activity, sedentary lifestyle was noted in 9 patients et 7 patients had a normal daily activity. The evaluation of the response based on imaging firstly and histological examination.

**Conclusions**
The nutritional status of patients with cancer requiring neoadjuvant chemotherapy was relatively preserved. Functional impairment, the presence of anorexia, appear to be independent predictive factors of quality of life in patients who will recievied neoadjuvant chemotherapy.

**PAGET’S DISEASE OF THE NIPPLE: WITH CONCOMITANT BREAST TUMOR: ABOUT 10 CASES**

M. Bouhani*, S. Sakhri, H. Bouaziz, A. Goucha, R. Chargui, M. Driss. Salah Azaiez Institute of Oncology, Surgical Oncology, Tunis, Tunisia

10.1136/ijgc-2021-IGCS.98

**Objectives**
Paget’s disease is an uncommon breast malignancy and often misdiagnosed, it is associated with underlying in situ or invasive breast cancer. The objective of this study is to identify the type of underlying cancer and specify these characteristics.

**Methods**
Nine patients with Paget’s disease who were admitted to our hospital were analyzed retrospectively.

**Results**
Our study included nine patients. Six patients were menopaused. Only seven patients presented with clinical findings suggestive of Paget’s disease of the breast. The mean size of the tumor was 36mm and axillary lymph node were found in seven cases and Mammography and ultrasonography were performed in all 16 patients and ultrasonography, of the nine mammographic studies, three were negative, in the others cases it showed suspected opacity in three cases, pleomorphic microcalcifications in four cases and both opacity and microcalcifications in three cases. Four patients had multifocality or multicentricity. Modified radical mastectomy was performed in seven patients, mastectomy and sentinel lymph node dissection in two cases in two, and wide local excision with lymph node dissection in one patient. Pathological findings were ductal carcinoma in situ (DCIS) (n = 4), invasive ductal carcinoma (IDC) (n = 1), invasive lobular carcinoma (n = 1), DCIS with IDC (n =4). All tumors had a high nuclear grade.

**Conclusions**
Patients with Paget’s disease of the breast have a high incidence of an underlying breast carcinoma. Most of the patients in this study presented late and were more likely to have positive mammograms.
