and less expensive. Nevertheless, based on a 25% and 15% rate of false positivity and negativity respectively, consideration should be given to confirm MSI IHC status for all patients by molecular analyses.

**Results**

She stayed at the intensive care unit for one day and formed as part of maximal secondary cytoreduction. Resection of bulky paraaortic lymph nodes, partial resection of the duodenum, and duodenojejunostomy were performed. Metastasectomy along with the infrarenal vena cava, resection of bulky paraaortic lymph nodes, partial resection of the vertebro-aortic area. Metastasectomy along with the infrarenal vena cava in a patient with recurrent ovarian cancer.

**Methodology**

A 68-year-old woman was admitted with a gross abdominal mass. She has been diagnosed with stage I, grade 1 endometrial cancer, and underwent a primary staging surgery 2 years ago. The magnetic resonance imaging revealed a 43x39x49 mm abdominal mass involving vena cava inferior. Also, positron emission tomography scan showed a 45x47x50 mm metastatic lymph node extending to the aortocaval prevertebral area. Metastasectomy along with the infrarenal vena cava, resection of bulky paraaortic lymph nodes, partial resection of the duodenum, and duodenojejunostomy were performed as part of maximal secondary cytoreduction.

**Results**

She stayed at the intensive care unit for one day and discharged without any grade 3 or 4 adverse event in postoperative period.

**Conclusion**

Secondary cytoreduction for endometrial cancer with no residual disease is a major impact on survival, and maximal cytoreduction is necessary in selected cases. The management of this condition should be performed with expert multidisciplinary teams in gynecological oncology.

**Introduction/Background**

Endometrial cancer is one of the common malignant tumors of the female reproductive system. The recurrence and 5-year overall survival rates of patients with FIGO I-II are 2–15 and 74–91%, respectively. Secondary cytoreductive surgery is associated with improved overall survival in patients with recurrent disease. This video aims to present metastasectomy along with the infrarenal vena cava in a patient with recurrent ovarian cancer.

**Methodology**

A 68-year-old woman was admitted with a gross abdominal mass. She has been diagnosed with stage I, grade 1 endometrial cancer, and underwent a primary staging surgery 2 years ago. The magnetic resonance imaging revealed a 43x39x49 mm abdominal mass involving vena cava inferior. Also, positron emission tomography scan showed a 45x47x50 mm metastatic lymph node extending to the aortocaval prevertebral area. Metastasectomy along with the infrarenal vena cava, resection of bulky paraaortic lymph nodes, partial resection of the duodenum, and duodenojejunostomy were performed as part of maximal secondary cytoreduction.

**Results**

She stayed at the intensive care unit for one day and discharged without any grade 3 or 4 adverse event in postoperative period.

**Conclusion**

Secondary cytoreduction for endometrial cancer with no residual disease is a major impact on survival, and maximal cytoreduction is necessary in selected cases. The management of this condition should be performed with expert multidisciplinary teams in gynecological oncology.

**Introduction/Background**

The primary aims of this study were to assess the molecular characterization of endometrial cancer (EC) patients with low volume metastasis (LVM) in the sentinel lymph node (SLN) and to identify the molecular predictors of recurrence among those patients.

**Methodology**

Patients with EC and LVM (isolated tumour cells (<0.2 mm) – micrometastasis (≥ 0.2 < 2 mm)) who underwent surgery from August 2014 to November 2020 and had subsequent molecular characterization were identified among four referral centres worldwide. Patients with adnexal involvement and FIGO stage IV were excluded. The molecular analysis included immunohistochemistry for p53 and MMR proteins and Sanger sequencing for POLE exonuclease domain. ECs were classified into four molecular classes (POLEmut, MMRd, p53abn, and NSMP).

**Results**

Among 101 patients, the molecular classification showed 56 NSMP, 31 MMRd, 13 p53Abn, and 1 POLEmut. Of 12 non-endometrioid cases, 11 were p53abn. Overall, 15 patients experienced a recurrence, and the median follow-up for the remaining patients was 3.1 (IQR, 2.0–3.8) years. The 3-year RFS was 90.4% (95% CI 95%, 81.8–99.9%), 82.1% (95% CI, 69.0–97.8%) and 65.6% (95% CI, 43.2%–99.7%), for the NSMP, MMRd, and p53Abn classes, respectively. No recurrence was observed in the POLEmut class. The overall RFS analysis between the three classes was comparable (p=0.11), and the comparison between p53abn class and the other classes did not reach a significant difference (p=0.07).

On univariate analysis, the presence of micrometastasis (p=0.02), non-endometrioid histology (p=0.02), lymphovascular space invasion (p=0.04), and positive peritoneal cytology (p=0.005) were significant predictors of recurrence.

**Conclusion**

Among EC patients SLN-LVM, there is a low rate of POLEmut tumours. Our results confirmed that traditional pathological features have a strong impact on prognosis among SLN-LVM patients. We did not observe significant impact of the molecular classes on the risk of recurrence, however further studies are needed.
