conservatively (preservation of the uterus and at least a part of one ovary) to promote subsequent fertility were specifically analyzed.

**Results** Between 1971 and 2017, 212 patients were identified and followed-up. Among these patients, 65 underwent conservative treatment; eight patients had invasive implants. Among patients treated conservatively, 38 (58%) patients recurred. Twenty-eight recurrences were observed under the form of borderline tumor on the spared ovary and/or noninvasive implants, but eight patients had a recurrence under the form of invasive disease. Compared with radical surgery, the use of conservative treatment (p < 0.0001) was a prognostic factor on disease-free survival (DFS), but without an impact on overall survival (OS). Nevertheless, three deaths occurred. Twenty-four pregnancies (13 spontaneous) were observed in 20 patients (29 patients wanted to become pregnant).

**Conclusion** In this series collecting the largest number of patients undergoing conservative surgery for stage I-II/IIA SBOtS, spontaneous pregnancies can be achieved after conservative treatment of advanced-stage disease, but the recurrence rate is high and three deaths were observed. These patients were spared their fertility but with a high rate of recurrence. Uncertainties regarding the safety of conservative treatment should be exposed to these patients.

**TRANSVAGINAL SINGLE PORT LAPAROSCOPIC FOR LEFT OVARIAN CYST REMOVAL AND BILATERAL TUBAL ANASTOMOSIS**

Ling Min, Lin Chen. Obstetrics and Gynecology, West China Second Hospital of SChuan University, ChenDu,SChuan, China

**Introduction/Background** Atypical endometrial hyperplasia (AEH) is an obligate precancer of the endometrium, which in terms of standard treatment, like the treatment of endometrial cancer (EC), involves the removal of the uterus. By the time of the primary diagnosis of AEH and EC, 5–7% of women are below 45 years at diagnosis have not completed childbirth. In these cases, the use of alternative therapies to preserve fertility and the possibility of delayed motherhood is very relevant. The aim of this study was to evaluate oncologic and reproductive outcomes in young women with AEH/EC, who underwent fertility-sparing treatment.

**Methodology** The study included data from 64 patients (AEH – 48, EC – 18) who were treated at NN Alexandrov National Cancer Centre (November 2017 – April 2022). The median age was 33 (range 20–42) years. After performing hysteroscopy, contrast agent was found in both oviduct and diffused in pelvic cavity. The patient was reexamined three months after operation:TVS: No abnormality was observed in uterus and bilateral appendages.HSG: Contrast agent was found in both oviduct and diffused in pelvic cavity.

**Conclusion** Transvaginal single port laparoscopic surgery fully embodies the concept of ‘transvaginal natural passage’, which is more minimally invasive, effective and safer than traditional open laparoscopic surgery. On the premise of strictly mastering the indications, it can be used for micro non-invasive surgical treatment of gynecological diseases.
