Introduction/Background Presenting the method of laparoscopic anterior rectal resection and ureteroplasty in the case of deep infiltrating endometriosis (DIE) retransplantation of the ureter. Proper function of the bowel and ureter were protected by fibrine glue. The bladder was isolated from the rectum by the trocar incision. The result of the surgery was complete realising from the pain and tailorsurgery on colon and ileum due to low grade neoplasma of appendix.

Methodology 28 year old lady with the history of dyschezia 9/10, dysmenorrhoea 9/10, dyspareunia 6/10, dysuria 7/10, infertility, left huge hydrenephrosis which were explained by urologist as a consequence of anatomical variation of the vesicula. She had the trial of cystoscopic ureteric JJ stent insertion prior to planned surgery with no success. 2 weeks later she had done laparoscopic surgery.

Results She had done segmental resection of the anterior rectum with the end to endrecto- sigmoid colon anastomosis due to 6 cm nodule of the rectum, the intraduodenal insertion of the JJ stent to the left ureter after cutting the wall of the ureter 10 cm from the bladder due to impossible JJ cystoscopic stenting with simultaneous retransplantation of the left ureter. All procedure was done in control of vascularity by ICG both in the uretero-bladder were protected by fibrine glue. The bladder was isolated from rectum by the flap of omentum. 5 weeks after surgical procedure the JJ stent was removed from the ureter. Proper function of the bowel and ureter were proved in control visit – 6 weeks after surgery.

Conclusion Laparoscopy is a perfect method for tailored and radical surgery in DIE and multiorgans surgery with all advantages of the minimally invasive access. Complete realising of the pain was huge success of the surgery.

PROTECTED LAPAROSCOPIC LARGE OVARIAN CYST ASPIRATION – A FIVE STEPS ALTERNATIVE TO LAPAROTOMY

Houssein El Hajj, Carlos Martinez Gomez, Adrien Boscher, Mathilde Duchateau, Delphine Hudry, Eric Leblanc, Fabrice Narducci. Gynecologic Oncology, Oscar Lambret Cancer Center, Lille, France

Introduction/Background In this video, we describe a five-step surgical technique allowing to safely incise and aspirate the content of large ovarian cysts through a single port laparoscopic incision. This allows performing laparoscopic oophorectomy instead of large xiphopubic laparatomies.

Methodology A Stepwise demonstration of the technique. Results Ovarian masses, especially cysts, are common gynecological conditions. However, depending on their size, large adnexal cysts are usually managed with transverse or midline laparotomies. This is to prevent cyst ruptures and abdominal contamination and ensure the oncological safety of the procedure. Different leak-proof aspiration techniques were described in the literature allowing for safe large cyst aspiration and adnexitomy through a mini-laparotomy incision or via laparoscopy (2,3,6–10). We describe a five steps surgical technique allowing for closed aspiration of ovarian intracystic fluid and adnexitomy while respecting oncological safety.

Interventions Step 1: Perform diagnostic laparoscopy to rule out peritoneal carcinomatosis contraindicating this procedure then after cyst exposition, thoroughly dry the cyst wall.

Step 1 Bis: Cut the cuff of a sterile glove to prepare a 46 square piece of membrane.

Step 2: Place a protective gauze, then apply the surgical glue to the ovarian cyst wall followed by the glove/membrane application. Perform a purse suture through the glove/membrane and the ovarian wall superficially to ensure further adhesion and prevent ovarian fluid spillage.

Step 3: Incise the ovarian wall then introduce the aspiration cannula and tighten the purse suture to aspirate the cystic fluid.

Step 4: After aspiration is complete, tighten the suture and close the glove to guarantee a closed space and prevent abdominal contamination.

Step 5: Perform laparoscopic oophorectomy or cystectomy. Safely remove the specimen in an endoscopic retrieval bag through the trocar incision.

Conclusion This technique allows safe laparoscopic large ovarian cysts resections while respecting oncologic safety and preventing intraabdominal spillage and contamination.

LAPAROSCOPY IS A PERFECT METHOD FOR TAILORED AND RADICAL SURGERY IN DIE AND MULTIORGANS SURGERY WITH ALL ADVANTAGES OF THE MINIMALLY INVASIVE ACCESS. COMPLETE REALISING OF THE PAIN WAS HUGE SUCCESS OF THE SURGERY

Introduction/Background Presenting the method of laparoscopic anterior rectal resection, partial sigmoid colon resection, right hemicolectomy and extended hysterectomy in the patient with deep infiltrating endometriosis (DIE) diagnosed with coexisting of low grade appendiceal mucinous neoplasm (LAMN).

Methodology 37 year old lady with the history of multiple laparoscopic and laparotom intervention due to endometriosis and infertility qualified to laparoscopic intervention.

Results She had done laparoscopic segmental resection of the sigmoid colon and anterior rectum resection with end to end anastomosis, total extended hysterectomy, right hemicolectomy with side to side anastomosis, cystectomy with protective JJstenting of both ureters due to massive adhesiolyis of the ureters. In histopathology: multifocal endometriotic infiltration of the bowel with the bigendometrotic nodules on rectum, sigmoid colon and cecum, low grade appendiceal mucinous neoplasm.
