Conclusion The MTD of the triple combination was established and the study met its secondary endpoint of initial efficacy; however, significant cytopenias were noted with this regimen, which may limit further development.

2022-RA-466-ESGO LONG-TERM RESPONDERS (LTR) TO RUCAPARIB IN RECURRENT OVARIAN CANCER: A SUB-GROUP ANALYSIS FROM THE RUCAPARIB ACCESS (RAP) PROGRAM IN SPAIN BY GEICO

Introduction/Background Rucaparib is a PARPi approved as maintenance (MTN) for platinum (Pt)-sensitive recurrent HGOC, and as treatment (Tx) for BRCA-mutated recurrent HGOC patients. Real-world data about LTR patients from the RAP is analyzed here.

Methodology A retrospective GEICO study was performed at 22 hospitals that treated patients within the RAP. Women with HGOC received rucaparib (600 mg BID) in the MTN, Tx Pt-sensitive or Tx Pt-resistant setting. In this subanalysis, long-term response was defined as progression-free survival (PFS) ≥12 months for the MTN group and ≥6 months for the Tx group.

Results In the study 51 patients were recruited: 18 received rucaparib as MTN and 33 as Tx. In the MTN group, 6 patients (33.3%) were LTR. Of them, 2 patients (33.2%) harbored BRCA or RAD51C mutations. The median number of prior lines was 3 (2–6), being ≥5 in 33.2%, 66.6% had measurable disease and 50.0% achieved PR to prior Pt-based chemotherapy. In the Tx group, 10 patients (30.3%) were LTR. All of them harbored BRCA and/or RAD51C mutations. The median number of prior lines was 6 (2–9), with 60.0% receiving ≥5 prior lines, 60.0% were Pt-resistant and 60.0% had measurable disease. The median PFS of LTR was not achieved in the MTN group and was 10.9 months (95% CI: 7.0–16.7) in the Tx group. Adverse events (AE) of any grade were reported in 66.6% of LTR within the MTN group and in 100.0% within the Tx group, while AE of grade ≥3 occurred in 16.6% and 50.0%, respectively. No new safety signals were detected. At present, 3 and 1 patients are still receiving rucaparib as MTN and Tx, respectively.

Conclusion A durable response was achieved in a notable proportion of patients, despite their unfavorable conditions at treatment initiation. The safety profile of rucaparib in this real-world setting is consistent with that previously reported.

2022-RA-567-ESGO THE GENEVA HRD TEST: CLINICAL VALIDATION ON 469 SAMPLES FROM THE PAOLA-1 TRIAL

1Yann Christnat, 2Lisa Ho, 3Sophie Clément, 4Catherine Genestie, 5Jalid Sehouli, 6Antonio Gonzalez-Martin, 7Ursula Denison, 8Keiichi Fujisawa, 9Ignace Vergote, 10Germana Tognon, 11Sakari Hetanen, 12Eric Pujade-Lauraine, 13Isabelle Ray-Coquard, 14Thomas A McKee.

Clinical Pathology Division, Geneva University Hospitals, Geneve, Switzerland; 2University hospitals leuven and Leuven Cancer Institute, Leuven, Belgium; 3Sakari Hetanen, 4Eric Pujade-Lauraine, 5Isabelle Ray-Coquard, 6Thomas A McKee.

Methodology As part of the ENGOT HRD European Initiative, a subset of the PAOLA-1/ENGOT-ov25 phase 3 trial was analyzed in the Geneva University Hospitals with the Onco-Scan™ CNV Assay and an in-house algorithm developed using TCGA data. Results were compared to Myriad myChoice Genomic Instability Score (GIS) with respect to the progression-free survival in the Olaparib+Bev and placebo+Bev arms.

Results The analysis of the TCGA cohort revealed that a normalization of the number of LST (large-scale state transitions) by the number of whole-genome doubling events allows a better separation and classification of HRD samples than the Myriad GIS. On the 469 PAOLA-1 samples, the Geneva test yielded a lower failure rate than Myriad (10/469 vs 59/469 inconclusive results) and positive and negative agreement values of 96% (204/213) and, respectively, 81% (159/197). In Geneva HRD-positive samples, the hazard ratio (HR) was 0.40 (95% CI: 0.28–0.57; figure 1). For Myriad, the HR was 0.35. In BRCA wild-type and Geneva HRD-positive samples, the HR was 0.53 (Myriad: 0.41). Of note, in this subpopulation the Geneva test and the Myriad test yielded a similar 1-year PFS (87% and 88%) but a different 2-year PFS (52% vs 60%).

Abstract 2022-RA-567-ESGO Figure 1
Conclusion The proposed test is a viable alternative to the Myriad myChoice HRD test and can easily be implemented in a clinical laboratory for routine practice. The performance of the tests is similar in terms of hazard ratio but the lower failure rate of the Geneva HRD test allows a 10% increase in the number of patients receiving a conclusive laboratory result.

**Introduction/Background** The surgical approach to hysterectomy for ovarian cancer has remained largely unchanged since Hudson described the en-bloc resection of fixed ovarian tumors using a retrograde technique in 1968. When a colorectal resection is required for optimal debulking, anastomotic leak remains a significant concern. While the traditional techniques used to evaluate for anastomotic perfusion lack accuracy, data from a recent systematic review and meta-analysis favours the use of ICG intra-op to reduce the incidence of anastomotic leak and associated need for re-intervention.

**Methodology** With the use of surgical footage, this video aims to present the surgical steps to a Hudson procedure with colorectal resection, ending with the use of ICG fluorescence to assess the perfusion of the colorectal anastomosis and ureters.

**Results** The surgical approach can be summarized in the following ten steps: (1) retroperitoneal dissection of the vascular pedicles and ureters, and transection of the IP ligament; (2) ureterolysis and transection of the IP ligament; (3) dissection of the paravesical and pararectal spaces; (4) lateral and pre-vesical peritoneum; (5) ureterolysis and transection of the ureterine vessels; (6) colpotomy; (7) mesorectal dissection and distal rectal transection; (8) proximal rectosigmoid transection; (9) vaginal vault closure and colorectal anastomosis; and distal rectal transection; (10) proximal rectosigmoid transection; (6) colpotomy; (7) mesorectal dissection and pre-vesical peritonectomy; (4) ureterolysis and transection of the IP ligament; (2) following ten steps: (1) retroperitoneal dissection of the vascular pedicles and ureters, and transection of the IP ligament; (2) the risk of anastomotic leak in colorectal surgery, and may be of interest in gynecologic-oncologic surgery.

**Conclusion** This video presented 10 reproducible steps to perform a Hudson procedure with colorectal resection for ovarian cancer. The use of ICG as an adjunct to assess the vascularization of the colorectal anastomosis appears to reduce the risk of anastomotic leak in colorectal surgery, and may be of interest in gynecologic-oncologic surgery.

**Introduction/Background** Low-grade serous carcinomas (LGSC) are associated with better prognoses compared to their high-grade serous (HGSC) counterparts. Nevertheless, we are confronted with a challenging treatment, since the median age upon diagnosis is younger, standard platinum-based chemotherapy is less effective and, most importantly, it has still not been as well studied as HGSC. The purpose of this ongoing study was to examine patients’ perception and assessment regarding their disease and therapy as well as the level of information among women with LGSC and borderline ovarian tumors (BOT).

**Methodology** A questionnaire was developed based on the experiences of previous EXPRESSION-trials and provided to patients with LGSC and BOT. The hard-copy-version was converted into an online database and statistically analyzed via SPSS-Software.

**Results** From March 2019, 321 patients with LGSC and BOT from eighteen German clinics and gynecological practices participated in the survey, 90 (28%) with LGSC and 231 (72%) with BOT. While nearly all patients (97.8% LGSC; 94.3% BOT) had primary surgery, 58% of LGSC patients received adjuvant chemotherapy. Patients indicated the attending physician as the main source of information (81% LGSC; 85% BOT). The majority were pleased with the explanation about their illness and therapy. Significantly more BOT-patients were not aware of their tumor stage during initial diagnosis.
