study series, supporting the clinician to integrate output analysis (Morphonode-SP).

Conclusion Our findings indicate that Morphonode Predictive Model is a simple and observer-independent tool. It could be easily integrated in the clinical routine for preoperative stratification of vulvar cancer patients.

2022-RA-1300-ESGO MULTICENTER EXPERIENCE ON SENTINEL NODE MAPPING IN VULVAR MELANOMA EVALUATION OF CLINICAL IMPACT

Introduction/Background Melanoma of the vulva is a rare disease, often burdened by a poor prognosis. It is essential to define the optimal treatment in early stage disease. This multicenter retrospective study investigates the role of preoperative lymphoscintigraphy and sentinel node biopsy (SNB) and the impact of SNB on loco-regional control and survival in vulvar melanoma patients with clinically negative nodes (cN0).

Methodology All women treated between July 2013 and March 2021 were evaluated. Inclusion criteria consisted in: (i) histologically proven vulvar invasive melanoma, (ii) a Breslow thickness of 1-4 mm and (iii) cN0 at preoperative evaluation. Patients selected underwent a preoperative lymphoscintigraphy followed by SNB with or without inguinofemoral lymphadenectomy. DFS and OS were assessed by the Kaplan-Meier method.

Results Eighteen women were included for a total of 28 groins studied. Planar images showed 51 sentinel nodes (SNs) in the enrolled inguinal regions. SNs were identified in all cases. Metastatic SNs were found in 5 patients (27.7%) for a total of 8 metastatic nodes in 7 groins (25%). Recurrent disease was diagnosed in 10 (55.5%) patients at 3 to 30 months: 7 were SN-negative, among which no specific groin recurrence was observed; 3 were SN-positive, among which 2 patients died of disease after 26.2 and 33.8 months, respectively. The overall mortality rate was 0% for SN negative and 40% in SN positive patients. OS and DFS at 36 months were 62.5% and 19.2%, respectively. The median DFS was 18.0 months (95% CI, 10.3–30.0).

Conclusion Lymphoscintigraphy followed by sentinel lymph node biopsy in patients with vulvar melanoma is feasible and allows adequate assessment of the stage of disease. Negative SNB is associated with low risk of groin relapse and good survival rate. Further prospective multicenter studies are needed to evaluate the criteria for clinical application.

2022-RA-1376-ESGO INTRODUCTION OF CARE BUNDLE IN VULVAL CANCER

Fatma Mohamed AlWahaibi, Heather Agnew, Ugochukwu Umeanozie, Ian Harley, Stephen Dobbs, Hans Nagar, Elaine Craig, Mark McCormiskey. Gynecology Oncology, Belfast City Hospital, Belfast, UK

clinical interventions would likely improve peri-operative outcomes. Aim of the study was to identify and quantify morbidity and mortality associated with VC surgeries. These data would be taken forward, after implementation of the care bundle, as baseline for comparison as to the efficacy of the intervention. Literatures and guidelines review will be undertaken to assist with the construction of the care bundle.

Methodology Patients who underwent curative surgery for VC from 2017–2018 at Belfast City Hospital were selected. Patients were followed up for 3 years postoperatively

Results 43 patients underwent major VC surgery. Data were available for 27 patients. Average age was 67.2 years. Mean body mass index 28.2 kg/m². All patients had squamous cell carcinoma except one with melanoma. All were stage 1a–II. All patients received pre-operative prophylactic antibiotics. 37% received post-operative antibiotics for 3–15 days. All vulvar wounds were closed using 2.0 vicryland 3.0 monocryl except one patient had clips. Groin wounds were closed using clips in 50% of the cases. Sentinel lymph node was used in 25.9%. Regarding drains: 62.4% had drain which were removed within 7 days. Urinary catheter was removed within 7.3 days. Laxatives were used in 29.6% postoperatively. Mean hospital stay was 12.1 days. Rate of readmission 14.8%, wound dehiscence 11.1%, hematoma 3.7%, infected lymphocyte 11.1% and cellulitis 22.2%. VC recurrence was 11.1% and death within the follow-up period was 22.2%. None related to surgery.

Conclusion Major VC surgeries are associated with high morbidity. Variety of strategies employed by clinicians regarding antibiotic therapy, wound closure, drains, urinary catheter and laxatives. Evidence-based, team agreed selection of uniform interventions as ‘care bundle’ would potentially lead to standardization of care and improvement in morbidity. We will present summary of evidence pertaining to creation of such a bundle and present our initial prospective results following its implementation.

Introduction/Background Malignant melanoma is an aggressive tumor of the skin and mucous membranes that develops in melanocytes. Mucosal melanoma is an extremely rare tumor. It represents 0.03% of all cancers. Its location in the female genital tract is an extremely rare location. The diagnosis is often initially unknown and is made at a late stage. Its management is not codified, with several therapies proposed, particularly for metastatic melanoma. Its evolution is unfavorable with frequent visceral metastases and a very short survival. The discovery of a c-Kit mutation suggests that c-Kit inhibitors, such as imatinib or sunitinib, may improve survival.

Conclusion Primary malignant melanoma of the female genital tract is an extremely rare location. The diagnosis is often initially unknown and is made at a late stage. Its management is not codified, with several therapies proposed, particularly for metastatic melanoma. Its evolution is unfavorable with frequent metastases and a very short survival. The discovery of a c-Kit mutation suggests that c-Kit inhibitors, such as imatinib or sunitinib, may improve survival.

Abstract 2022-RA-1458-ESGO Figure 1

Relative errors were computed as \( \frac{A-A_0}{A_0} \) and are shown in Figure 1B. The eKare system was most accurate.
