pelvic exenteration from 2012 to 2021 for surgical and survival outcomes.

Results A total of 65 patients were included. Mean age of the patients was 46.17 (18–70 years). Predominant primary sites were rectum, ovary and cervix. All were curative intent resections. Majority of patients underwent supra-levator posterior exenteration. Mean duration of surgery was 342.30 min (150–600 min). Mean blood loss was 614.89 ml (100 ml to 2500 ml). Length of hospital stay was on average 11.16 days (5–45 days). R0, R1 resection rates were 97.5% and 2.5% respectively. In-hospital mortality was 3.6%. Urinary leak rates (5.6%), GI anastomotic leak (7.27%), enteric fistula (9.09%). Follow up data was available for 38 patients, 14 expired due to disease (26.9%), with median time to death from surgery of 14.3 months (2.3–57.53 months). Overall, 58.3% of the patients were alive at the end of 3 years (with available follow up data).

Conclusion Long term outcomes are favourable with pelvic exenteration in select subset of patients with acceptable morbidity.

10.1136/ijgc-2022-ESGO.130

Introduction/Background The objective of this study is to evaluate the survival and describe the recurrence of patients with early stage cervical cancer treated with ‘Schaumheim radical hysterectomy’ by minimally invasive surgery (MIS) at the Oscar Lambret Center.

Methodology From 01/1999 to 12/2018, we included all patients managed by minimally invasive surgery at the Oscar Lambret Center for early stage cervical cancer with tumor size < 4 cm (FIGO stage IA1 with emboli at IIA1). The primary endpoint was the 5-year overall and recurrence-free survival rates in these patients. Overall survival (OS) and Disease-Free Survival (DFS) were estimated from the initial biopsy using the Kaplan-Meier method. Hazard ratio (HR) was estimated with 95% confidence interval (CI95%).

Results A total of 239 patients were included. All patients underwent bilateral pelvic lymphadenectomy before radical hysterectomy. Preoperative image adapted brachytherapy (IABT) was performed in 125 patients. The 5-year overall and recurrence-free survival rates were 92% (95% CI 87.4–95%) and 86.9% (95% CI 81.6–90.7%), respectively. The multivariate analysis showed 2 associated factors to risk of recurrence: previous conization (HR = 0.21 (CI95% 0.06–0.70); p=0.01) and tumor size > 30 mm (HR = 2.26 (CI95% 1.08–4.73); p=0.031). We observed 33 recurrences, including 22 deaths due to disease. The recurrence rates were respectively 7.5% for tumor ≤20 mm, 12.9% for tumor between 20–30 mm, and 24.1% for tumor >30 mm.

Conclusion MIS is safe and for tumor size ≤20 mm with a very low rate of local recurrence; for tumors size >30 mm relapse rates are high and should be treated with concomitant radiochemotherapy and brachytherapy. For sizes between 20 and 30 mm, further data are needed to define management recommendations. Previous conization allow us to have a better accuracy regarding the tumor size in order to tailor the treatment.

10.1136/ijgc-2022-ESGO.131

Introduction/Background We compared survival outcomes of minimally invasive surgery (MIS) and open surgery for radical hysterectomy (RH) in early-stage usual-type adenocarcinoma (UAC) and adenosquamous carcinoma (ASC) of the cervix.

Methodology From the two centers’ cervical cancer cohorts, cervical cancer patients with 2009 FIGO stage IB who underwent Type C RH between 2007 and 2021 were identified. Patients with UAC and ASC were included in the analysis after pathologic review according to the updated WHO Classification of Tumors. Patients’ clinicopathologic characteristics and survival outcomes were compared by surgical approach.

Abstract 2022-RA-1462-ESGO Figure 1

Results A total of 161 patients were included in this analysis: 136 and 25 had UAC and ASC, respectively. No differences
