Conclusions LSR is associated with tumor growth, invasion, metastasis, and poor prognosis in EC. Anti-LSR mAb is a potential therapeutic agent which induces apoptosis and shows a significant antitumor effect in EC.

**Objectives** Ovarian preservation in young endometrial cancer (EC) patients is controversial and requires further consideration. We aimed to assess the risk for ovarian cancer (OC) following EC in patients who underwent ovarian preservation as part of the initial EC staging and to characterize this group of patients.

**Methods** With permission of the Surveillance, Epidemiology and End Results (SEER) program of the United States National Cancer Institute, clinicopathological and prognosis information of women diagnosed with EC and following OC were analyzed. Patients were divided into groups: Group A – EC patients that had BSO performed; Group B – EC patients that had ovarian preservation performed. Incidence of OC and survival rates were compared.

**Results** 383 patients diagnosed with OC following EC were documented. Of them 260 patients had a known BSO performance status. Incidence of OC did not differ between groups (IRR 1.07, CI 0.83–1.39, p=0.59). Survival rates were significantly shorter in ovarian preservation patients compared to patients with BSO performed as part of their EC staging and treatment. However, when analyzing by age, in women diagnosed with EC up to age of 49 years old, no differences in survival rates were found comparing the two groups.

**Conclusions** Ovarian preservation in EC patients under the age of 49 years may be considered safe, with no impact on OC incidence or survival, benefiting a longer natural hormonal status. In EC patients who went through ovarian preservation a close follow-up for at least 7 years from the EC diagnosis is recommended.

**Objectives** The purpose of this study was to evaluate the role of vaginal hysterectomy for the treatment of patients with low-risk endometrial cancer.

**Methods** We retrospectively reviewed the medical records of patients who underwent vaginal hysterectomy for treatment of endometrial cancer or its precursor lesions at a single center in São Paulo, Brazil. Medical data obtained included comorbidities, pre and postoperative histological diagnosis, perioperative outcomes, adjuvant treatments and oncological and surgical follow-up.

**Results** Medical records from 34 consecutive patients who underwent vaginal hysterectomy for endometrial cancer or its precursor lesions between April 2019 and November 2021 were analyzed. Mean age was 61.9 years and body mass index (BMI) was 34; 76.5% of patients were obese (BMI ≥ 30). Medical comorbidities including hypertension (67.7%) and diabetes (35.3%) were commonly noted. Sixty-one percent of patients had two or more comorbidities. Mean operative time and hospital stay were 109 minutes and 1.2 days, respectively. Four (11.8%) patients had conversion of surgical route to laparotomy due to vascular trauma (2 cases) or anatomical difficulties (2 cases). No other major complications were found. Patients undergoing surgical conversion had greater uterine volume (226.8 vs 110.4 ml, p=0.036), longer operative time (116 vs 98 min, p<0.0075) and hospital stay (56.8 vs 23.2 hours, p<0.0001). Twenty-eight patients had low-grade endometrioid carcinoma; three (10.7%) of them received adjuvant...
